To Allah ﷻ, my parents, wife, and families who support my studies

وَهُوَ الَّذِي خَلَقَ اللَّيْلَ وَالنَّهَارَ وَالشَّمْسَ وَالْقَمَرَ كُلٌّ فِي فَلَكٍ يَسْبَحُونَ

*And it is He who created the night and the day and the sun and the moon; all  
[heavenly bodies] in an orbit are swimming (21:33)*

## ACKNOWLEDGMENTS

Praise be to Allah ﷻ, may praise and peace be upon the Messenger of Allah, upon his family, his Companions and those who follow his guidance. I would like to express my gratitude to Allah ﷻ for His tawfiq and hidayah so that I can complete this thesis with a good result. Secondly, thanks to my parents Dra. Siti Fathiyah Banser and Dani Kusnandar, SE for their prayer all the time. My wife Sofa Tsani Aflacha, S.Si whose support, times, and much cheers for my son and daughter, Musa & Maryam.

Prof. Stewart Greenhalgh for his immense help and patience in teaching and advising this research. Dr. Sannlinn Ismail Kaka and Dr. Umair Bin Waheed for the guidance and help of some suggestions on this research.

Special thanks to Dr. Abdullatif Al-Shuhail for his help and support to my study in KFUPM. Dr. Abdulaziz Al-Shaibani and all Geosciences faculty and staff for all support, guidance, and attention to my study. Thank you to all CPG crews: Eng. Ayman Al-Lehyani, Eng. Abdulatif Ashadi, Adnan Al-Mubarak, Ahmed Al-Shaibani, Khalid Abdurrahman, Hameed Bhay, Mojtaba, and special thanks for Dr. Lamidi Babalola for the field trip.

Dr. Tauhid Nur Rahman, Agi Sugilar, ST., Ben Hilman, ST., Jodi Caesardana, ST., Faris Pramadhaniwali, S.Si., Mojtaba, for all your help in the differential GPS data acquisition and processing. All Indonesian and PPMI Dhahran squads, Mas Andy, Uda Septri, Mas Pram, Tausif Bhay, Uda Yose, Bang Yusri, Kang Adha, Bang Yusron, and special thanks for my roommate Kang Jemi for his prayers, support, and good culinary taste.

Finally, I hope this research can be beneficial for all the readers. If you have any suggestions or corrections for this manuscript, please kindly send it to [hanifgeos@gmail.com](mailto:hanifgeos@gmail.com).

## ABSTRACT

Full Name : Muhammad Hanif

Thesis Title : Near-surface Investigation of The Dammam Dome on KFUPM using The Gravity Method

Major Field : Geophysics

Date of Degree : May 2018

This thesis presents a near-surface investigation to explore the fault structures and cavity potential in the Dammam Dome. The gravity acceleration has been measured on the Dammam Dome in KFUPM campus. The total acquisition area is approximately 5 km<sup>2</sup> with the grid station is roughly 50 meters. The instruments are using Scintrex CG-5 Gravimeter and Leica GPS 1200+. Basic data correction such as tide, drift, latitude, free-air, Bouguer, and terrain has been carefully done to generate complete Bouguer anomaly (CBA) map. The regional field was then removed from the total gravity field using a spatial filtering technique to obtain the residual anomaly map due to near-surface geological variations. The second vertical derivative (SVD) map of the residual field was calculated and analyzed to better define geological faults and other features such as cavities. Sixty-seven dominant fault structures were interpreted. The dominant structural trends are NW-SE and NE-SW, with average fault strike directions of N 39° W and N 48° E. From the second vertical derivative and fault dip modeling analysis in the 4 fault lines, the dominant type of faults in the area are thrust faults and the fault dip are 21°, 15°, 28°, and 67°. These structures as well as the sand filled subsurface cavities are most probably controlled by the doming mechanism and dissolution.

## ملخص الرسالة

الاسم الكامل: محمد حنيف

عنوان الرسالة: قرب التحقيق السطحي لقبة الدمام في جامعة الملك فهد باستخدام طريقة الجاذبية

التخصص: جيوفيزياء

تاريخ الدرجة العلمية: مايو 2018

تقدم هذه الأطروحة تحقيقات في المنطقة القريبة من السطح لاستكشاف هياكل الصدوع وإمكانات التجاويف في قبة الدمام. تم قياس تسارع الجاذبية في قبة الدمام في حرم جامعة الملك فهد للبترول والمعادن. وتبلغ المساحة الإجمالية لجمع البيانات حوالي 5 كيلومتر مربع ، بشبكة محطات تبلغ حوالي 50 مترًا. تمت عملية جمع البيانات باستخدام Scintrex CG-5 Gravimeter و Leica GPS 1200+. تم إجراء تصحيح البيانات الأساسية مثل المد والجزر وخطوط العرض وبوغير والتضاريس بعناية لإنشاء خريطة شذوذ بوغير الكاملة (CBA) ثم تم إزالة الحقل الإقليمي من حقل الجاذبية الكلي باستخدام تقنية الترشيح المكاني للحصول على خريطة الشذوذ المتبقية بسبب الاختلافات الجيولوجية القريبة من السطح. تم حساب وتحليل المشتقة الرأسية الثانية (SVD) للحقل المتبقي من أجل تحديد الصدوع الجيولوجية و الملامح الجيولوجية الأخرى مثل التجاويف بشكل أفضل. تم تفسير البيانات بسبعة وستين صدع جيولوجي. الاتجاهات الهيكلية السائدة هي NW-SE و NE-SW، مع متوسط اتجاهات الصدع N 39 W و N 48 E. من التحليل للمشتقة الرأسية الثانية و نمذجة انحدار الصدع لخطوط الصدع الأربعة ، فإن النوع المهيمن من الصدوع في المنطقة هي صدوع الدفع ، وانحدارات الصدوع هي 21 و 15 و 28 و 67. هذه الهياكل بالإضافة إلى التجاويف تحت السطح المملوءة بالرمال هي على الأغلب خاضعة لسيطرة آلية التفكيك والالتحام.

الكلمات المفتاحية: قبة الدمام ، تجويف ، جاذبية ، صدع ، قريب من السطح ، المملكة العربية السعودية

# CHAPTER 1

## INTRODUCTION

### 1.1 Preamble

Dammam Dome is situated in Dammam city, Eastern Province of Saudi Arabia. Unlike any other Saudi Arabia terrain, this region is unique due to the Hormuz Salt formation growth under this formation. This ellipsoid shape of group formation is rising 7 m/Ma (Weijermars, 1999). The terrain is indicated by the build-up of carbonate rocks on the flat extent of the Dammam Peninsula. There was situated the first discovery of a hydrocarbon-bearing structure within the Arabian mainland. The Standard Oil Company of California (SOCAL) first discovered oil in Dammam Dome from drilling the Dammam-7 Well in March 1938 (Al-Fahmi et al., 2014). Outside the Kingdom of Saudi Arabia, the structure is associated with a massive hydrocarbon reservoir in Kuwait (Milton, 1967), the surface exposure in Qatar (Al-Saad & Ibrahim, 2002), and similar to the elongated Awali Dome on the Island of Bahrain.

The main rock structures of the Dammam Dome are fractured carbonates with joints, karst features, and small-scale reverse faults (Al-Fahmi et al., 2014). Dissolution on the carbonate rocks structure can cause a karst phenomenon and resulting in subsurface cavities (Weijermars, 1999). The geological units have also been subject to faulting due to compressional stress from Zagros Orogeny, tangential stress associated with the dome's growth or development of local structures (Al-Fahmi et al., 2014)

Knowing the subsurface properties at shallow as well as greater depths is important for geoscientists as well as civil and petroleum engineers. The deeper structure controls to a large extent the hydrocarbon accumulations whilst variations in the surface topography and near-surface geology can corrupt the seismic images from the reservoir. This case can lead to seismic horizon picking errors (Setiyono et al., 2015), in addition to creating geo-hazard disasters (Khaldouy et al., 2015).

Near-surface exploration using geophysical methods can be applied to delineate the subsurface structure of an area, especially for mapping potential cavities and faults. For example, ground penetrating radar (Chamberlain et al., 2000; Momayez et al., 1996), electrical resistivity tomography (Gambetta et al., 2011; Metwaly & Alfouzan, 2013; Putiška et al., 2012), seismic refraction and reflection (Fiore et al., 2013; Pernod et al., 1989), transient electromagnetic methods (TEM) (Guoqiang et al., 2004), and microgravity surveying (Bishop et al., 1997; Butler, 1984; Pánisová & Pašteka, 2009; Styles et al., 2005) are all useful techniques for locating anomalies in the subsurface.

## **1.2 Literature Review**

The literature records many studies describing qualitative investigation of cavities by utilizing geophysical tools. The gravity method is a non-destructive and passive remote sensing technique that utilizes changes in the Earth's natural gravitational field (caused by anomalous subsurface masses or density variations) to elucidate subsurface structure. It is especially sensitive to lateral subsurface density variations (Nettleton, 1971). Some researchers have already applied the method for investigating cavities. A qualitative

approach of gravity exploration for detecting shallow cavities in large caverns in Iraq was presented by Colley (1963). Butler (1984) developed microgravity analysis using the derivatives of the gravitational potential and concluded that the procedure is an effective means for delineating air and sediment filled cavities. Martín et al. (2011) integrated the techniques of regional residual separation using polynomial fitting, global geopotential model, and spectral analysis and successfully detect the cavities.

Some geotechnical studies of the study area began in the 1980s, including the evaluation of potential geohazards caused by solution cavities in shallow limestone beds (Abdullatif, 2010; Abu Taleb & Egeli, 1981; Crosch et al., 1985; Davies & Lord, 1980; Jado & Johnson, 1983). Weijermars (1999) reported fractures and joints in the Middle and Lower Rus units. The near-surface studies on this area are limited to ground penetrating radar and has found its capability to delineate cavities on 1-2 m depth (Al-Shuhail et al., 2004b).

Table 1 shows the summary of karstification on the Dammam Dome (Al-Fahmi et al., 2014).

Table 1 Summary of Karstification Data (Al-Fahmi et al., 2014)

No.	Karst Features	Location		Area (square meters)	Formation
		North	East		
1	Filled cave	26°18'52"	50°04'47"	1,000	Dam
2	Synform	26°18'48"	50°05'56"	8,987	Rus
3	Synform	26°19'23"	50°06'37"	Uncertain	Rus
4	Synform	26°18'59"	50°06'45"	20,255	Rus
5	Sinkhole	26°19'12"	50°07'05"	4,115	Rus
6	Sinkhole	26°19'03"	50°07'58"	300	Rus
7	Sinkholes	26°18'43"	50°08'19"	400	Dammam
8	Sinkhole	26°18'17"	50°07'23"	16,323	Rus
9	Synform	26°18'16"	50°06'24"	14,020	Rus
10	Sinkhole	26°18'21"	50°06'07"	650	Rus

My study adds to the characterization of near-surface density and structure model of the Dammam Dome on the KFUPM campus. It focuses on finding possible large structures (e.g fractures and karst features) and interpreting the lateral density distribution with its patterns. The methodology integrates the gravity survey with high accuracy of topography mapping acquired by differential GPS and laboratory data on rock features (eg; density) from the literatures.

### 1.3 Study Area

The study area is a part of Dammam Dome that situated on the King Fahd University of Petroleum & Minerals (KFUPM) campus, Dhahran city, Kingdom of Saudi Arabia (See Figure 1 & Figure 2). The bounding coordinates are 26°19'5.31'' N to 26°17'34.68'' N and 50°09'0.18'' E to 50°8'18.75'' E. The study area bordered with the blue line on Figure 2 is approximately 5 km<sup>2</sup> area. The gravity measurements were acquired mainly

on the roads and access paths inside the KFUPM campus both within the academic and housing complexes.

Figure 1 Location of Dammam Dome (on the red box) situated on the Eastern Province of Saudi Arabia from Google Earth® 2018

Figure 2 3D map view of study area (blue line bordered) taken from Google Earth ® 2018

In this study, a total of 500 field measurements of vertical gravity, roughly in a regular grid of 50 x 50 m has covered the area. The gravity data were acquired using Scintrex CG5 gravimeter and the topography control was carried out with a Leica 1200+ differential GPS. See Figure 3 below for the station position and the interpolated elevation model on the study area.

Figure 3 Station position and the elevation model on the study area

## 1.4 Motivation

The presence of faults and subsurface cavities poses an enormous hazard possibility because they have a collapse potential. This constitutes a risk to people as well as land and building damage. The delineation of faults and cavities are important aspects in the

geotechnical applications. Drilling is a common method of site investigation to detect the physical parameter of subsurface, but it has some limitation in the cost and the depth reached. To overcome the problem, non-invasive and cost effective geophysical methods can be used for near-surface fault. Due to importance of subsurface properties, a joint inversion approach of geological and gravity data is proposed to map the subsurface rock distribution and to detect the cavities potential in the study area.

## **1.5 Thesis Objectives**

To date there have not been any attempts using the gravity method to image the near-surface structure and cavity potential on the Dammam Dome. However, the gravity technique has been applied widely elsewhere for subsurface cavity detection, but mainly using a qualitative approach. In this thesis, the objectives are to quantitatively map the near-surface structure and cavity potential using the gravity method. It is intended to estimate the subsurface density distribution of the area. Therefore, the aim of this work is to analyze and interpret the near-surface structure and likelihood of cavities occurrence of Dammam Dome on KFUPM campus by studying the fault structure. Furthermore, the gravity data will be inverted with the rock density and structure constrains from laboratory measurements and literatures to get the fault dip estimation.

## **1.6 Thesis Outline**

This MSc thesis consists of six chapters. Apart from this first introductory chapter; it comprises the following chapters:

### **Chapter 2**

Covers the literature review of the gravity method and the geological background from previous investigations on both the geophysical and geological side.

### **Chapter 3**

Explains the methodology, how the data are acquired, quality controlled, and processed together.

### **Chapter 4**

Details the synthetic model generation for fault dip in the study area.

### **Chapter 5**

Explains the result over the target area as well as the interpretation.

### **Chapter 6**

A summary and recommendations for future work.

## **CHAPTER 2**

### **GEOLOGY OF THE DAMMAM DOME**

#### **2.1 Geological Setting of the Dammam Dome**

The geological units are Tertiary (T) and Quaternary (Q) as shown in Figure 5. The former is sub-divided into the Rus (Tr), Dammam (Tdm), Hadruk (Th), and Dam (Td) formations. The Quaternary deposits which are labeled using two lower case letters which express the predominant lithology or facies: sabkha (Qsb), coastal deposits (Qcd), and eolian sand (Qes). There are also areas of reclaimed land (Re), which are composed of landfill materials. On the study area, it was indicated that there are Rus Formation and Umm Er Radhuma (UER) Formation.

##### **Rus Formation**

Rus Formation as part of Lower Eocene has been divided into three members: lower, middle, and upper part. The lower part of formation shows alteration of marls and thin dolomitic limestone beds with abundant slumps and geodes. The middle Rus consists of a vuggy weathered, well-jointed calcarenite with abundant mud balls. The upper Rus consists of fine-grained chalky limestone with few marls and clay layers at the top. The thickness found on the Dammam Dome outcrop is 50 m.

Figure 4 Stratigraphic column of Rus Formation (Al-Fahmi et al., 2014)

### Umm Er Radhuma Formation

The formation is the lowermost Cenozoic formation. Umm Er Radhuma (UER) Formation was described as a 3m-thick section of vuggy dolomite located about 488 m east of Jabal Umm ar Ru'us in a topographically low area along the core of small anticline (Tleel, 1974). The other outcrop is located within the KFUPM campus and was reported to be part of the upper UER from its distinctive lithology (Weijermars, 1999). The thickness can reach up to 500 m meter on the subsurface (Alsharhan et al., 2001).

Figure 5 Geological map of Dammam Peninsula. Indicated geological boundaries are between the Lower and Upper of Rus Formation, between Rus and Dammam formation and Quaternary and Sabkha outlines (Weijermars, 1999).

## **2.2 The Karst System of Dammam Dome**

The karst phenomena exist over large areas of the eastern part of Saudi Arabia (Hariri, 2013). They are formed as solution features such as sinkholes, collapse dolines and caverns. Caves are repositories for sediments moved in to form the surface and for sediments derived from within the cave (Al-Fahmi et al., 2014). The landforms are particularly associated with carbonate and evaporite formation of the Arab, Hith, Sulaiy, Umm er Radhuma (UER), Rus, Dammam, Dam, and Salt Dome formations.

The presence of karst within the UER Formation (marked as Location 2 in Figure 6) can be inferred from synforms within the lower Rus Unit at some areas in Dammam Dome. The small sinkholes are a bowl shaped morphotype but the larger ones have indefinite shape and are simply referred to as synforms. The large synforms are identified from some exposed units that dip with some angle to the flat surface (Crosch et al., 1985). It is also identified from bedding inclination measurements for some rock strata dipping in an opposite direction to the general gentle dip of the dome locations where bedding is expected to dip away from the central region of the dome.

In conclusion, the karst features can be identified by exploring the possible potential for dipping layer or fault feature.

Figure 6 Map of high resolution topography showing 10 m contour interval of the Dammam Dome main area (Weijermars, 1999)

The existence of karst around the Dammam Dome has been demonstrated by some researchers using excavation methods such as in KFUPM (Jado and Johnson, 1983) and North Dhahran (Crosch et al., 1985). It shows that the location is subject to potential hazard from sinkholes, dolines, or caverns. Abdullatif (2010) has mapped several types of cavities from the outcrop of the Rus Formation.

## **CHAPTER 3**

### **METHODS AND PROCEDURES**

#### **3.1 Overview**

The detection of subsurface cavities is possible using certain geophysical methods, especially the gravity method provided by the cavity is sufficiently large and not too deep. The method may detect the presence of the cavity (air-filled, water-filled or sediment-filled) provided there is enough density contrast between the cavity fill and the surrounding rock layers. In this chapter, I review the gravity method, the surveying procedure, and the elevation and position determination, which are crucial for making corrections to the observed gravity data and the interpreted result.

The gravity method measures the lateral variation in the vertical component of the gravitational field at the surface of the earth. This variation is caused by the subsurface density distribution. Moreover, this method is appropriate to investigate the subsurface geological structures such as detecting faults, geological boundaries and mapping basins. Cavities are one of the features that can be mapped by this method. This structure can be a void or filled by a mass of sediments. Therefore, they usually have a lower density than the surrounding rock layer and therefore produce a negative gravity anomaly.

Newton's Law of Gravitation is the basic law that addresses gravity measurements:

$$F_g = G \frac{M_1 M_2}{R^2} \quad (1)$$

where  $F_g$  is the gravitational force due to the two masses  $M_1$  and  $M_2$  a distance  $R$  apart, and  $G$  is the universal gravitational constant ( $6.672 \times 10^{-11} \text{ Nm}^2/\text{kg}^2$ ).

From the equation above the gravity acceleration ( $g$ ) due to a body of mass  $M$ ,

$$g = \frac{GM}{R^2} \quad (2)$$

Gravitational acceleration  $g$  is measured in Gal where  $1 \text{ Gal} = 1 \text{ cm/s}^2 = 0.01 \text{ m/s}^2$ .

However, most targets of interest usually produce much smaller anomalies, especially in engineering and environmental studies. Therefore, these studies require surveys with micro-Gal resolution ( $1 \text{ micro-Gal} = 0.001 \text{ mGal}$ ). The term microgravity survey is used instead of gravity survey which is generally used for regional gravity surveys.

## 3.2 Gravity Surveying

### 3.2.1 Data Acquisition

In addition to the anomalous subsurface mass variation, which is the objective of the gravity survey, the gravity observations are the combined effects of all regional geological features plus instrumental effects, position on the Earth's surface, elevation and terrain effects plus planetary attraction. Theoretical formulae, geological data, and empirical observations are used to remove the extraneous effects of temporal and spatial variations in the gravity field which are unrelated to the subsurface geology. After removing all the unintended effects, the target features can be isolated (Hinze *et al.*, 2013). Figure 7 is a flow-chart which illustrates the methodology of gravity interpretation.

Figure 7 Flow-chart showing the components involved in the interpretation of gravity data and their relationship (Hinze et al., 2013)

To observe the gravity field, it needs some basic tools for doing the measurements as shown in Figure 8. The main one is the gravimeter which measures relative gravity. The other tools are for position determination and leveling (Figure 9).

Figure 8 Instruments used in the data acquisition: a) Scintrex CG5 gravimeter on the tripod, b) remote & attached GPS

Figure 9 a) Differential GPS Leica1200+ GPS base and b) rover instrument

### 3.2.2 Data Reduction

The raw gravity data need to be corrected for instrument drift and earth tide effect. The latter is the gravitational attraction due to the Sun and the Moon, which varies systematically throughout each day. After correction, we obtain the observed gravity value ( $g_{obs}$ ).

#### 1. Drift Correction

The instrument drift correction is largely due to stress relaxation in the elastic system due to the stretching of the quartz fiber in the gravity-meter. After an initial stabilization period, it can be considered a linear function of time, see Figure 10.

Figure 10 Left: gravity reading from the survey stations (grey dot) should be corrected by total of drift and tide correction reading from the base station (black dot) to get the observed gravity value. Right: Tide and drift correction in a graph showing the variation of corrections in terms of time (Greenhalgh & Marescot, 2013).

#### 2. Tide Correction

The gravitational effect of the sun and the moon not only produce a changing shape of ocean surface or fluid tides but also distort the shape of the earth (Telford et al., 1990). As its effect is much less for rocks than for water, the amount of external forces is much

less than the ocean distortion. The ocean tides have amplitudes in the range of meters, but the solid earth tides are in the range of centimeters. The theoretical gravity tide correction is calculated using the venerable formulas of (Telford et al., 1990).

To get the value of observed gravity ( $g_{obs}$ ), the gravity reading at the survey station should be corrected by the amount of tide and drift correction that is done in the base station periodically.

### 3. Complete Bouguer Anomaly

The complete Bouguer Anomaly (CBA) is the gravity anomaly after application of a series of corrections to consider the known variations in the field, such as due to latitude, elevation etc. It can be formulated as follows (Hinze et al., 2013)

$$CBA = g_{obs} - g_{\theta} + FAC - BC + T \quad (3)$$

$g_{obs}$  is the observed gravity reading after earth tide and drift corrections obtained by repeated measurements at a fixed base station. The Bouguer anomaly basically measures how gravity changes from one station to another.

From the equation (3),  $g_{obs}$  must be corrected by several factors, was explained below:

#### a. Latitude correction ( $g_{\theta}$ )

Gravity varies as a function of latitude on the surface of the reference ellipsoid. A Chebychev approximation is used to measure the effect with a maximum error of 0.004 mGal (Telford et al., 1990),

$$g = 978.03185 (1 + 0.005278895 \sin^2 \theta + 0.000023462 \sin^4 \phi) \text{ Gal} \quad (4)$$

This formula assumes that the points are on the surface of the reference ellipsoid. There are free air and Bouguer effects need to be calculated if there is difference in elevation of the reference elevation.

In many exploration surveys covering limited areas, the station locations are not referenced to global latitude. As a result, the latitudinal effects on the stations of the survey are referenced to a single station (usually the base station) and determined by assuming a linear gradient of the normal gravity as a function of north–south distance (distance is not far from extremities of area). This gradient in mGal/m can be determined by differentiating above equation with respect to north-south distance  $x_{N-S}$  so that

$$\frac{\partial g_\theta}{\partial x_{N-S}} = 0.8144 \times 10^{-3} \sin(2\theta) \quad (5)$$

assuming a mean radius for the Earth of 6,367.45 km and the spherical coordinate.

#### **b. Free air correction**

The attraction of the Earth can be considered to be the same if its mass were concentrated at its center. So, the further out from the center of the earth the less the gravity. All stations must be corrected for this effect relative to a datum level (eg: sea level). The elevation difference of the gravity-meter from the datum must be determined. The correction will be calculated as:

$$g_0 - g_{obs} \cong \Delta g \cong -2 \frac{g_0}{R} \quad (6)$$

$$FAC = 0.3085 h \quad (7)$$

where  $g_0$  represent the attraction of gravity on the geoid and the  $g_{obs}$  is the observed gravity at the station, while  $h$  (in meter unit) represents the difference in elevation of  $g_0$  and  $g_{obs}$ .

### **c. Bouguer correction**

This correction is dependent on the slab of rock which lies between the datum level and the  $h$  station elevation (in meter unit). It will have the opposite sign to the free air correction. The correction depends on the  $\rho$  average density (in  $\text{g/cm}^3$  unit) of the material between the station and datum according to the formula:

$$BC = 0.04185 \rho h \quad (8)$$

Densities of rocks  $\rho$  as shown in Figure 11 below are determined by certain factors such as rock type, mineralogy, degree of compaction, etc. The Bouguer density used for the correction in this study is  $2.3 \text{ g/cm}^3$  because the residual anomaly lies in the Rus and UER Formation which has average density of  $2.3 \text{ g/cm}^3$  (Abdullatif, 2010). The laboratory test is measured from the outcrop samples on each formations has been done by Abdullatif (2010) to get the precise density of the formation, shown on Table 2.

Figure 11 Natural densities (saturated bulk density) of igneous, metamorphic, and sedimentary rock types (after Hinze et al., 2013).

Table 2 Summary of laboratory testing result for the Lower and Middle Rus Formation carbonates studied in outcrops (after Abdullatif, 2010).

Formation	Lower Rus			Middle Rus		
Geomechanical	Average	Minimum	Maximum	Average	Minimum	Maximum
Parameter						
Point load Strength I Index (Mpa)	5.20	0.56	24.3	6.90	0.5	13.21
Uniaxial Compressive Strength (Mpa)	100.10	12.12	506	152.92	15	288.86
Porosity (%)	10.39	5	16	8.83	5	14
Dry Density (g /cm³)	2.28	1.7	2.52	2.56	2.14	2.86
Permeability (md)	84.57	5.08	316.27	58.35	2.98	278.72
Young's Modulus <i>E</i> (Mpa)	42748	4047	183236	80322	13879	207503
Poisson's Ratio	0.22	0.10	0.38	0.21	0.10	0.35
Schmidt Hammer	33	12	54	50	36	60

#### d. Terrain correction

This correction is added to compensate for the difference between the actual surface topography and assuming flat infinite slab as in the Bouguer correction. The terrain correction is always positive and requires a detailed elevation map of the entire area. It can often be ignored when topography is gentle. It will remove the effect of hills by adding its upward attraction at the station and compensates for valleys by adding the attraction it would exert at the station if filled with rock.

The correction is extremely tedious and usually done using Hammer charts as shown in Figure 12, which require the average elevation in each compartment and the known distance to each station.

Figure 12 Hammer chart to measure terrain correction on gravity survey (Telford et al., 1990)

The usual procedure is to divide the area into compartments and compare the elevation within each compartment with the station elevation (Telford et al., 1990). This can be

done by outlining the compartments on transparent sheet as shown on Figure 10 overlying a topographic map. Based on its radius this correction is divided into inner zone  $r_1$  and outer zone  $r_2$ , and  $n$  indicates the total zone.

$$T = 0.04191 \frac{\rho}{n} \left( r_2 - r_1 + \sqrt{r_1^2 + z^2} - \sqrt{r_2^2 + z^2} \right) \quad (9)$$

After all the data reduction done, the Bouguer anomaly can predict the density distribution in the subsurface as shown in the Figure 13.

Figure 13 The basic idea of gravity surveying. The lower panel shows a cross-section through the ground. The red circle (right) represent denser region and blue circle (left) indicates less dense region. The above panel shows the Bouguer anomaly that measured at the surface (Pumphrey, 2014).

### **3.2.3 Station Elevation and Position Determination**

Observed gravity is affected by differences in the rock density on the subsurface but it is also affected by the elevation and ground surface. Hence, to see slight differences in density contrast, the elevation measurement must be done in an accurate way. For small scale surveys, for example 1 km distance, the heights need to be measured to an accuracy of  $\pm 1$  cm. To get this accuracy the altitudes must be surveyed in the traditional manner using theodolite and levelling stave or we can apply the recent technology of differential GPS.

By using differential GPS methods, we can get up to  $\pm 5$ -10 mm accuracy by using static method. Due to the limited time of study, I use the kinematic techniques to get the efficient elevation data. Figure 10 illustrate how one concept of altitude measurement using real time kinematic (RTK) differential GPS to get accuracy of  $\pm 1$  cm.

In this study, the methods were applied using Leica 1200+ GPS instrument to obtain the accurate position and elevation of the station (See Appendix B).

### **3.3 Regional Residual Anomaly Separation**

The Bouguer gravity data are presented in either map or profile form for analysis and interpretation, depending on the objectives and coverage of the survey and the attributes of the observed anomalies. These data are the summation of all anomaly sources regardless of their depth or distance from the observation point and any errors in the processing of the data (Hinze et al., 2013).

The gravity anomaly (A) resulting from the reduction of observed gravity data thus consists of three separate components; the residual anomaly ( $A_r$ ) which is the target of the survey, the regional anomaly (AR) which contains the larger spatial wavelength components of the gravity related to deeper geological features, and the noise (N) which is spatially smaller than the residual. That is,

$$A = A_r + AR + N \quad (10)$$

Noise may originate from the instrumentation system and the observer, the reduction and processing of data, and geophysical interpretation. These effects can be minimized by adding together a series of observations in which measurements include a coherent signal with random errors or signals superimposed. This procedure, commonly referred to as stacking, attenuates the random errors or noise by a factor of  $\sqrt{n}$  with respect to the coherent signal, where n is the number of elements in the series. This procedure is used widely in geophysics to minimize random errors or noise (Hinze et al., 2013).

Generally, the noise, N, is negligible and disregarded, in which case the anomaly of interest, the residual gravity anomaly, is simply

$$A_r = A - AR \quad (11)$$

In actual practice, the subtraction is directly performed graphically or arithmetically using polynomial filtering, spectral analysis, or indirectly performed by emphasizing the residual anomaly at the expense of the regional anomaly (Hinze et al., 2013).

Elimination of the regional gravity anomaly from the observed anomaly is a critical step in the identification and analysis of gravity anomalies. There are some methods to do this

separation such. Improper definition of AR can cause errors in the attributes of the residual anomaly, its amplitude, gradients, trend, etc.

### 3.3.1 Spectral Analysis

Spectral analysis is a process to identify the different spatial wavelengths (or wavenumbers) present in the Bouguer anomaly map, which in turn relate to depth information. The residual field can be separated from the regional field by a process of wavenumber filtering to retain only the large wavenumbers or small wavelength features. Besides that, the result from this analysis will be used for the window length in the moving average process. Spectral analysis uses the Fourier analysis mathematical method that is carried out on the selected profile line on the chosen gravity anomaly (Elkins, 1951)

The one-dimensional Fourier transform is used to transform any function from the spatial (or time) domain into the wavenumber (or frequency) domain. This transform is useful in geophysics because of the ease of convolving functions and filtering data in the wavenumber domain. The two-dimensional Fourier transform is equally useful for transforming and filtering map data, for example the gravity field as a function of distance east and north. The 2D forward and inverse Fourier transform is:

$$F(k_x, k_y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) e^{-i2\pi(k_x x + k_y y)} dx dy \quad (12)$$

$$f(x, y) = \left(\frac{1}{2\pi}\right)^2 \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F(k_x, k_y) e^{-i2\pi(k_x x + k_y y)} dk_x dk_y \quad (13)$$

where  $k_x$  and  $k_y$  refer to the 2D wavenumber in the x and y directions.  $f(x, y)$  is the function of gravity field as function of map coordinate x, y and  $i$  is the complex conjugate. A 2D power spectrum shows the wavenumbers (or their reciprocals, wavelengths) at which signals are most prominent on the map.

### 3.4 Second Vertical Derivative

The second vertical derivative (SVD) enhances near-surface effects at the expense of deeper anomalies. Second vertical derivatives are a measure of curvature of the Bouguer anomaly, and large curvatures are associated with shallow anomalies.

The second vertical derivatives can be obtained from the horizontal derivatives because the gravity field satisfies Laplace's equation

$$\nabla^2 g = \frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2} + \frac{\partial^2 g}{\partial z^2} = 0 \quad (14)$$

$$\frac{\partial^2 g}{\partial z^2} = -\left(\frac{\partial^2 g}{\partial x^2} + \frac{\partial^2 g}{\partial y^2}\right) \quad (15)$$

According to this equation, the second derivative of the vertical component of the gravity field outside the sources can be calculated by applying the operator  $O$  to  $g(x, y)$  (Buttkus, 2000),

$$O = -\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right) \quad (16)$$

$$\frac{\partial^2}{\partial z^2} g(x, y) = -\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right) g(x, y) \quad (17)$$

Application of the operator  $O$  to gravity field data  $g(x, y)$  with the 2D wavenumber spectrum  $G(k_x, k_y)$  yields

$$g(x, y) = O\{g(x, y)\} = -\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} G(k_x, k_y) e^{i2\pi(k_x x + k_y y)} dk_x dk_y$$

$$= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} 4\pi^2(k_x^2 + k_y^2) G(k_x, k_y) e^{i2\pi(k_x x + k_y y)} dk_x dk_y \quad (18)$$

Or in the wavenumber domain:

$$V(k_x, k_y) = 4\pi^2(k_x^2 + k_y^2)G(k_x, k_y) \quad (19)$$

The second derivative to the vertical component of the gravity field thus corresponds to a 2D filter with wavenumber response function

$$H(k_x, k_y) = 4\pi^2(k_x^2 + k_y^2) \quad (20)$$

The wavenumber response function  $H(k_x, k_y)$  is multiplied by  $G(k_x, k_y)$  to get vertical derivative in wavenumber domain  $V(k_x, k_y)$ . The resulting function then back transformed into the spatial domain  $v(x, y)$ . The averaging procedures is needed to avoid the amplification of measurement errors due to this method.

The purpose of second vertical derivative method to the gravity data is to identify the shallow structures, fault type and to estimate the fault dipping. The criteria used for determining whether a fault is normal or reverse are as follows (Reynolds, 1997):

$$\left| \frac{d^2 g}{dz^2_{max}} \right| > \left| \frac{d^2 g}{dz^2_{min}} \right| \text{ for normal faults} \quad (21)$$

$$\left| \frac{d^2 g}{dz^2_{max}} \right| < \left| \frac{d^2 g}{dz^2_{min}} \right| \text{ for thrust faults} \quad (22)$$

## **CHAPTER 4**

### **SYNTHETIC STRUCTURAL DIP GENERATION**

This chapter explains the synthetic fault model to estimate the fault dip in the study area. The combined analysis between the synthetic model and the second vertical derivative value can predict the fault dip of the structure.

#### **4.1 Synthetic Model Generation**

From the analysis of second vertical derivative value (SVD), the fault dip can be modelled based on the empirical formulation. Therefore, the fault model is built with various dip angle from 10 to 90 degrees. Assuming the minimum thickness of Umm Er Radhuma Formation on this study is 100 meters (Alsharhan et al., 2001) and  $0.25 \text{ g/cm}^3$  contrast density with the top in 20 meters depth and bottom in 100 meters depth. It is based on the estimation of the thickness of Rus Formations and depth of Umm Er Radhuma (UER) Formation (Al-Fahmi et al., 2014; Weijermars, 1999).

To model the background subsurface layer, the average density is obtained by the mean of measured density of the layers on the study area. The density for Lower Rus Formation is  $2.28 \text{ g/cm}^3$  or the average density value from the laboratory test and for Middle Rus Formation is  $2.14 \text{ g/cm}^3$  is the minimum density value from the laboratory test. All these tests has been done to 49 outcrop samples on the study area (Abdullatif, 2010). The density value for Umm Er Radhuma (UER) is  $2.56 \text{ g/cm}^3$  from the average density for

dolomitic limestone (Telford et al., 1990). The difference between the Umm Er Radhuma Formation and the average background density is  $0.25 \text{ g/cm}^3$  is used to model the synthetic fault model for the dip estimation.

Table 3 Background density on the study area for synthetic model generation

Formation	Density ( $\text{g/cm}^3$ )
Middle Rus	2.14
Lower Rus	2.28
Umm Er Radhuma	2.56
Average	2.31

See Table 3 for the explanation of subsurface density assumption for the modeling on the Figure 12.

Figure 14 Synthetic fault model in semi-infinite slab with fault dip  $90^\circ$ , 100 meters thickness and  $0.25 \text{ g/cm}^3$  contrast density

On the Figure 14, the synthetic model was built based on the geological features on the study area. It is built to get the idea of fault dip variations to the Bouguer anomaly value. The density contrast is plotted as  $0.25 \text{ g/cm}^3$  as the UER Formation consists of dolomitic

limestone which has average density of  $2.56 \text{ g/cm}^3$  and the resulting background layer has average density  $2.31 \text{ g/cm}^3$ .

Figure 15 Residual complete Bouguer anomaly of the synthetic model

To get the idea of change in dip angle, the synthetic model is modified in to different fault dips from 10, 20, 30, to 90 degrees. These generated synthetic models is then forward modelled to get the complete Bouguer anomaly response on the Figure 15. After getting the residual anomaly profile, the second vertical derivatives profile must be generated as the method is effective to map the fault edge and near-surface structure.

Figure 16 Second vertical derivative of the synthetic model

After getting the second vertical derivative profile shown in Figure 16, the normalized second vertical derivatives profile needs to be generated. This value will help us defined the fault dip in the study area and indirectly will define its fault type.

Figure 17 Normalized second vertical derivative for various fault dip angle

The normalized second vertical derivative profile in Figure 17 is generated by dividing the absolute maximum value of the second vertical derivative anomaly. This normalized profile is built to get the same scale of all dip model.

The value between the maximum and minimum value of each dip angle in this profile is called delta second vertical derivative ( $\Delta SVD$ ). The value is then plotted to get the relationship between the fault dip and  $\Delta SVD$ .

Figure 18 Synthetic fault dip angle relation with the delta second vertical derivative value

On Figure 18, the relation between the fault dip and the delta second vertical derivative map are plotted and is shown a good fit with the exponential model, refer to

Table 4. So, the model to predict the fault dip (y) from the delta second vertical derivative (x) is  $y=0.0986e^{3.434x}$ .

Table 4 Curve fitting model of the delta second vertical derivative synthetic model

Model	Formula	R <sup>2</sup>
I. Exponential	$0.0986e^{3.43x}$	0.94
II. Linear	$123x - 166$	0.83

## CHAPTER 5

### RESULTS AND ANALYSIS

#### 5.1 Bouguer Anomaly

The gravity data acquisition was carried out at 500 stations (see Figure 19) and then some data reduction explained in Chapter 2 was performed to correct the observed values and obtain the Bouguer anomaly (See Appendix A).

Figure 19 Map of gravity stations on the KFUPM Dammam Dome topography map. The green dots are stations position.

The Bouguer density used in generating the Bouguer anomaly profile is  $2.31 \text{ g/cm}^3$ , which is the average density determined by laboratory tests (Abdullatif, 2010). The interpolation of the model in this study is carried out using kriging and the resulting standard deviation was 1.57%.

Figure 20 Bouguer anomaly map showing the variation of gravity anomalies in the area

## 5.2 Terrain Correction

The Bouguer anomaly map needs to be corrected for terrain effects to eliminate the effects of topography and nearby buildings on the campus. From the differential GPS measurement, the maximum accuracy of 2 centimeters in position and elevations were acquired (Appendix B). The terrain correction was measured using the Digital Elevation Model from SRTM satellite provided by USGS which has 1-arcsecond or 30 m resolution with 5 m vertical precision (Elkhrachy, 2016).

The digital elevation model (DEM) map on Figure 21 is used to be an elevation control for topography of the surrounding station. The scope area of DEM map is enlarged from the border of study area to accommodate the terrain correction of the outermost stations.

Figure 21 Digital Elevation Map from SRTM satellite

Each station was terrain corrected using Hammer method resulting a terrain correction map as shown on Figure 22. We can see from the figure that the largest value 0.062 mGal of the correction is on the western side of KFUPM which dominated by the building and the hills.

Figure 22 Terrain correction of the study area derived from the Hammer chart method using DEM map. The value range is from 0.009 to 0.062 mGal

After getting the correction of terrain, the Bouguer anomaly profile is added by the amount of terrain correction in each station. The result is called complete Bouguer Anomaly (CBA) as shown in Figure 23 below.

Figure 23 Complete Bouguer Anomaly map, which is the Bouguer anomaly corrected for the terrain effects (units in mGal)

## 5.3 Regional-Residual Separation

### 5.3.1 Two Dimensional FFT Filter Descriptions

The spatial frequencies of the filters used in separating the field are specified in terms of wavelengths (distance in meters). Cut-off rates determine the sharpness of the filter and the tapering of the energy spectrum. A high value of the cut-off has the effect of removing high frequencies but causes ringing on the edges of large amplitude changes.

The two-dimensional Fourier transform is equally useful for transforming and filtering map data, for example the gravity field as a function of distance east and north. The 2D forward Fourier transform is:

$$F(k_x, k_y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) e^{-i2\pi(k_x x + k_y y)} dx dy \quad (23)$$

For extracting the regional anomaly, we filter as  $R(k_x, k_y) = F(k_x, k_y) D(k_x, k_y)$ , where  $D$  is the wavenumber low pass filter and subsequently return it to the spatial domain using the two-dimensional inverse Fourier transform:

$$r(x, y) = \left(\frac{1}{2\pi}\right)^2 \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} R(k_x, k_y) e^{-i2\pi(k_x x + k_y y)} dk_x dk_y \quad (24)$$

After getting  $r(x, y)$ , the regional anomaly in the spatial domain, we can derive the residual anomaly  $t(x, y)$  by subtracting the regional from the total gravity anomaly as:

$$t(x, y) = f(x, y) - r(x, y) \quad (25)$$

### 5.3.2 Data Preparation

To do this analysis, I used Oasis Montaj Geosoft® software. The pre-processing steps involve the preparation of the original spatial domain grid for filtering before the filters are applied. And then, the post-processing is aimed to return the filtered data to the same size and shape as the original grid and replacement of a regional trend.

Firstly, the  $n$ th-order trend or mean is removed from the gridded data to take our data and make the boundaries continuous for when we expand periodically (an implicit assumption of the discrete Fourier transform). And then the grid (which has now had the

trend removed from it) is expanded to prepare for the Fourier transform. The Fast Fourier Transform (FFT) in this study used the Cooley-Tukey algorithm.

The Cooley-Tukey algorithm requires grids to be of dimension 2 raised to an integer power  $n$  (i.e. 2, 4, 8, 16, 32, ...). So, if we have a grid which is 29 x 15 it would be expanded to 32 x 16 in order to meet the requirements of the FFT. Normally one has to pad with zeros out to higher  $n$  values to avoid wraparound effects with the FFT

Alternatively, the grid is then filled with dummies values using maximum entropy to fill the new expanded dimensions such that the grid becomes smoothly periodic. Since the grid is a single square/rectangular tile and copies of the tiles are laid out edge to edge, the grid pattern should smoothly match from tile to tile. The processing parameter shown on Table 5.

Table 5 Data preparation parameter for regional residual separation

Parameter	Value
Type of trend surface to remove	2 <sup>nd</sup> order
Trend based on	Edge points
% Expansion	10
Grid fill method	Maximum Entropy

Figure 24 Radially averaged power spectrum. Butterworth filter is applied for regional anomaly

On Figure 24, the wavenumber unit is cycles per 1000 m while the filter axis on the right-hand side showing the fraction of spectrum value that is filtered from the whole spectrum. The blue line indicates its filter profile and its intersection with the whole spectrum (black line) obtained the resultant of spectrum profile for the regional anomaly (red line). The filter uses Butterworth filter to easily control the degree of filter roll off while leaving the central wavenumber fixed.

Figure 25 Radially averaged power spectrum. Butterworth filter is applied for residual anomaly

On Figure 25, the wavenumber unit is cycles per 1000 m while the filter axis on the right-hand side showing the fraction of spectrum value that is filtered from the whole spectrum. The blue line indicates its filter profile and its multiplication with the whole spectrum (black line) yields the resultant spectrum for the residual anomaly (red line). The filter used is a Butterworth filter to easily control the degree of filter roll off while leaving the central wavenumber flat.

### 5.3.3 Separation Result

Figure 26 indicates the regional anomaly on the study area. The anomaly value represents the deeper source density. While the residual anomaly on the Figure 27 represents the shallower anomaly. This residual anomaly will be used on the next analysis.

Figure 26 Regional anomaly

Figure 27 Residual anomaly from Butterworth filter

## 5.4 Second Vertical Derivatives

The second vertical derivative method of analytical regional – residual separation was applied to the available reduced data of the study area to calculate the second vertical derivative using Fast Fourier Transform (FFT). The complete Bouguer anomaly map was transformed the 2D spectral domain (Figure 28) and then filtered with second vertical derivatives. Finally, it was back transformed into the spatial domain (Figure 29).

Figure 28 Two-dimension power spectrum

This filter will enhance the structure on the study area especially for near-surface fracture. As the fault or fractures can be defined by the rapid change of second vertical derivatives curve, the line shown on Figure 25 was delineated to get the idea of fault types on each structure.

Figure 29 Second vertical derivative maps with the interpreted fault lines

## 5.5 Fault Type Determination

The analysis of second vertical derivative (SVD) is needed to confirm the vicinity of near-surface structure especially for fault structure. Using SVD, the structure is identified by its rapid change/contrast in the value. There is reduced probability of fault structures in the slight change values of the SVD.

Figure 30 The interpreted fault lines crossing perpendicularly with the fault structure illuminated by SVD

Figure 30 shows the SVD analysis on the study area. The interpreted fault lies perpendicular with the black lines. The structure of Dammam Dome is affected by compressional regime of Hormuz Salt. The growth on this salt diapirism has begun in Jurassic and Cretaceous time in response to tectonic extension that took place within Arabian plate (Al-Fahmi et al., 2014). The compressional regime from the Hormuz Salt

caused the radial or concentric structure on the above formation and can be indicated by NW & NE structure orientation (Hariri, 2013).

Based on SVD calculation, the value of absolute maxima curve is greater than its minimum absolute curve on the normal fault structure.

$$\left| \frac{d^2 g}{dz^2}_{max} \right| > \left| \frac{d^2 g}{dz^2}_{min} \right|$$

Vice versa, the fault structure is a reverse/thrusting fault structure in a greater value of minimum absolute.

$$\left| \frac{d^2 g}{dz^2}_{max} \right| < \left| \frac{d^2 g}{dz^2}_{min} \right|$$

Figure 28 explains the indicated second vertical derivative absolute maximum value |SVD max| and minimum |SVD min| on the Line-1

Figure 31 |SVD max| value indicated with red dot and |SVD min| value with the blue dot

Figure 32 to Figure 35 on the next pages show the profile of residual anomaly, second vertical derivative (SVD), and the normalized SVD for 4 lines.

Figure 32 Attributes of residual and SVD on the Line-1

Figure 33 Attributes of residual and SVD on the Line-2

Figure 34 Attributes of residual and SVD on the Line-3

Figure 35 Attributes of residual and SVD on the Line-4

Figure 32 to Figure 35, the profile line 1, 2, 3 are showing the thrusting or reverse fault structure but Line-4 showing the normal fault structure. These findings supports the geological research on the Dammam Dome that conclude reverse faults dominated the structure on the area (Hariri, 2013).

## 5.6 Fault Lineament Orientation

The fault lineament delineations on the second vertical derivative map are shown in Figure 26. The lineaments have been mapped to get an idea of the dominant geological stress pattern of the study area.

Figure 36 Interpreted fault structure on the residual map

On the Figure 36, there are 67 faults delineated in the zero value of second vertical derivative map. The interpreted direction of zero SVD value which separate the positive and negative anomaly is interpreted as the most probable fault structure. Those delineated fault structures then mapped to the rose diagram to get the dominant direction of tensional axis for the stress regime in the study area.

Figure 37 The sixty-seven faults orientation are delineated on the residual map. Left: The mean direction of total faults orientation is N 13° E, and the filtered two major directions N 39° W and N 48° E are shown by the red line

As shown on Figure 37, the delineation of 67 faults orientation resulting N 39° W in the NW fault direction and N 48° E in the NE fault direction. See Appendix C for the statistical detail of each orientation delineation.

The dominant direction of fault strike in the study are NW and NE. The results are matched with the study on the Dammam Dome using GIS analysis (Hariri, 2013), outcrop and geo-mechanical study (Abdullatif, 2010), and borehole logs (Al-Fahmi et al., 2014) as shown on Figure 38.

Figure 38 Various study on the dominant structures orientation on the Dammam Dome (Al-Fahmi et al., 2014). The red rose diagram was from satellite image study and the other from direct field studies. The study area is located on the green circle.

## 5.7 Fault Dip Estimation

Based on the empirical generalization formula for the synthetic model in Chapter 4, we can conclude the fault dip angle for those four interpreted faults.

Table 6 Estimated fault dip and fault type of 4 interpreted faults

<b>Fault Line</b>	<b>Delta Normalized SVD (mGal/m<sup>2</sup>)</b>	<b>Estimated Fault Dip (°)</b>	<b>Fault Type</b>
Line-1	1.56	21	Thrust Fault
Line-2	1.47	15	Thrust Fault
Line-3	1.65	28	Thrust Fault
Line-4	2.05	67	Normal Fault

On the Table 4, it can be concluded that the dominant structures on the study area are thrust fault. However, the normal fault found in the study area are a local effect of geological force in the dome structure.

The result of fault dip estimation from the synthetic model analysis is limited by several factors. As explained previously, the dip is obtained from an empirical based formula which assumes that the only unknown is dip, the other parameters (formation thickness, density, and depth) remaining fixed and known. In this case, deviation of 6% from the generated model will produce slight errors on the dip estimation. In the actual field situation, the parameters may vary due to local geology changes in the study area. For the purpose of simply assessing the geological fault trend of the study, such deviations are acceptable. However, for more advanced use, such as volumetric estimation or detailed modeling, a more refined approach is needed such as gravity inversion and or joint inversion with another geophysical technique.

## 5.8 Forward Modeling

As explained on the Chapter 3, the methodology for generating the forward model is Talwani algorithm (Talwani & Ewing, 1960). The forward modeling is built on the line where the potential cavities situated. On Figure 39 the delineated line was chosen due to the strong negative and positive anomaly on the residual map. This feature indicated the karst potential on the area.

Figure 39 Delineated line for forward modeling

Figure 40 The calculated residual gravity profile and its forward modeling result showing the formation density distribution

On the Figure 40, the profile of residual anomaly in the delineated black line is used to do a forward modeling. The density variation and lateral variation is interactively modified to get the best fit between the residual anomaly on the station (black dots) and the calculated profile (black line). The total misfit from the modeling is 0.5 mGal.

The lighter color of the formation on Figure 40 is indicated by 'K' letter to assign the karstified formation. The formation has  $1 \text{ g/cm}^3$  lower density than the surrounding layer. It is interpreted as probable karstified region. The most probable feature for that karstified region is cavity filled with partially saturated sand (Al-Shuhail et al., 2004a).

Table 7 The formation density and interpreted karstified formation density

Formation	Density (g/cm <sup>3</sup> )
Middle Rus	2.14
Lower Rus	2.28
Umm Er Radhuma	2.56
Middle Rus Karstified	1.14
Lower Rus Karstified	1.30
Umm Er Radhuma Karstified	1.56

The lower density on the karstified formation in the study area are interpreted as cavity filled with partially saturated sand. The karstified formation has lower density than the surrounding formation due to the less dense material filled on the cavity. The interpreted density of karstified formation shown on Table 7.

This feature is probably affected by the high concentration of fault structure on the profile. As the UER formation is a ground water reservoir in the Eastern Province area, most probably the fault on the study area is a good conduit for water that make the dolomite limestone on the formation dissolved (Al-Fahmi et al., 2014).

## **CHAPTER 6**

### **CONCLUSIONS AND RECOMMENDATIONS**

#### **6.1 Conclusions**

Some analysis and result has been interpreted in the previous chapters. Those conclude some important points of the research in the study area:

1. The second vertical derivative method indicates the near-surface structures in the study area are dominated by high concentration of fault structure.
2. Thrust fault is dominant in the near-surface as the second vertical derivative high value is greater than the lower value. This indicates the main force in the study area is due to the dome structure which resulting thrust fault. The presence of normal fault is a local structure affected by the main tensional stress.
3. The structure orientation delineated in the second vertical derivative map resulting the dominant NW and NE fault orientation in the study area. The average directions are N 48° E and N 39° W.
4. The empirical formula generation for fault synthetic model concluded the dominant structures are thrusting fault. In 4 interpreted fault lines the fault dip are consecutively: 21°, 15°, 28°, and 67°.
5. The karstified formation on the study area are interpreted as a model having a cavity filled with partially saturated sand

## **6.2 Recommendations**

To get the better result in studying the near-surface structure on this study area, there are some recommendations:

1. To get better results of forward modeling, the interface of the near-surface layer can be obtained by doing seismic refraction, resistivity, or TDEM surveying.
2. Use the inversion method to validate and enhance the forward model.
3. Do a joint interpretation using wider data range like seismic data, satellite or airborne gravity, which can be combined with the magnetic method.
4. Undertake drilling to tie the analysis to the geology and validate the model.

## **APPENDIX**

## **Vitae**

Name : Muhammad Hanif

Nationality : Indonesia

Date of Birth : November 10<sup>th</sup>, 1991

Email : hanifgeos@gmail.com

Address : Jalan Gegerkalong Girang Kiara 1 No. 29 Bandung

Postal Code: 40153, Indonesia

### **Academic Background:**

B.Sc of Geophysics, Institute Technology of Bandung (ITB), 2013

M.Sc of Geophysics, King Fahd University of Petroleum & Minerals (KFUPM), 2018

### **Publication:**

Hanif, M., Greenhalgh, S., Kaka, S.I. (2018). Gravity investigations of near-surface faulting and cavities of the Dammam Dome on the KFUPM campus, Saudi Arabia. Arabian Journal of Geosciences (submitted)
